Abstract

Background

Recurrent pregnancy loss affects 1 to 5% of women trying to conceive, I t has a significant impact at individual and social level.

Methodology

case-control study conducted at the research laboratory of the national center of neurological sciences, Khartoum, Sudan. All patients attending Ibrahim Malik teaching hospital and diagnosed with recurrent spontaneous abortion were included as case and healthy women at reproductive age were included as controls. The DNA was isolated by standard phenol chloroform extraction method, The PCR was done by using commercial thermal cycler machine with specific protocol. PCR products were sent for sequencing to Macro gene Europe Laboratory.

Results

494 bp of MTHFR(C677T) and 174 bp of MTHFD (rs2236225) (G19581A) alleles were detected after PCR. The PCR result of MTHFR(C677T) shows; 40 (90%) forMTHFR (C677T) allele was positive in the cases and only12 (24 %) were positive for the control group. For MTHFD (G19581A) allele 42 (95%) were positive in the case group and 14 (28%) were positive in the control. When compared between case and control there was highly significant differences. The sequencing results for MTHFR C677; single Base Exchange was found C>T in the case groups, when used the mutation taster software the mutation was predicted. For MTHFD (G1958A) in the case group tow single Base Exchange were found T>A and G>A, the mutation taster software was predicted T>A mutation.

Conclusion

According to this result the MTHF polymorphisms might become one of the main causes of unexplained diagnosis women with recurrent spontaneous abortion

Key words: recurrent pregnancy loss, dna, gene, mutation and polymorphism

Introduction

Recurrent pregnancy loss (RPL) is generally affect 1 to 5% of women trying to conceive. Recurrent pregnancy loss (RPL) is defined as two or more consecutive pregnancy losses before the 20th week of gestation [1,2].

The loss of pregnancy at any stage can be a traumatic experience and particular sensitivity is required in assessing and counselling couples with recurrent pregnancy loss. They are more susceptible to experiencing higher levels of depression, anxiety and feelings guilty than the general population. Therefore, these couples may benefit from regular contact and reassurance [3].

Although RPL has significant impact at individual and social level, there is insufficient screening methods for risks of recurrent pregnancy loss. Previous reproductive history is an independent predictor of future pregnancy outcome. The risk of a further miscarriage increases after each successive pregnancy loss, reaching approximately 40% after three consecutive pregnancy losses, and the prognosis worsens with increasing maternal age. previous live birth does not prevent a woman developing recurrent miscarriage [4].

Thrombophilia is known as a predisposition for thrombosis. Thrombophilia has two types inherited or acquired. About 40% of cases due to inherited [1]. Inherited thrombophilia has been shown to be a risk factor for reproductive disorders including recurrent pregnancy loss

Many thrombophilic genes have been reported as risks factor for recurrent pregnancy loss including methylenetetrahydrofolate reductase (MTHFR) [C677T] and MTHFR [A1298C].

Methylenetetrahydrofolate reductase catalyzes remethylation of homocysteine to methionine.

Homozygous C677T mutations of the MTHFR gene associated with high levels of homocysteine and this is a risk factor for thrombosis, as homocysteinemia can cause endothelial damage in blood vessels. Therefore, it affects the embryonic development and pregnancy success Folic acid and vitamin B12 is able to markedly decrease homocysteine levels [5,6,7].

This Study to search for relationship of recurrent pregnancy loss and MTHFR C677T and MTHFD (G19581A) variants.

Material and method

This was case-control study conducted at the research laboratory of the national center of neurological sciences (NCNS), Khartoum, Sudan during the period April to September, 2021to detect the possible MTHF gene polymorphisms among women with RSA

All patients attending obstetrics and gynecology unit at Ibrahim Malik teaching hospital and diagnosed with recurrent spontaneous abortion durina the aforementioned period were included.Women with more than three recurrent abortions were included in this study as cases and those healthy women at reproductive age were included as controls. Women with chromosomal abnormality, uterine anomalies, genital infections, and endocrinological disorder were excluded. The data was collected by using well stricture questionnaire. Ethical clearance for this study was obtained from ethical review committee, Faculty of Medical laboratory University of Medical Science and Technology, the participants was fully informed about the advantages and disadvantages before participation in the research (verbal informed consent). From each participant 3 ml of venous blood was withdrawn with minimal stasis from the ante-cubital vein using a dry sterile disposable syringe and needle. Blood samples were dispensed into sterile containers with Ethylene

Diamine Tetra-acetic Acid (EDTA). They were labeled with subject's age, sex and identification number and stored at -20°C for molecular analysis.

The DNA was isolated from peripheral blood leukocyte by standard phenol chloroform extraction method. Primers were designed by using Prime3 software. The forward primer for MTHFR 677 was designed as "5-GGTCAGAAGCATATCAGTCATGAG -3" and reverse as "5- CTGGGAAGAACTCAGCGAACTCAG -3" with product size of 494bp fragment. And MTHFD (rs2236225) forward primer "5-CTCCCAAAGTGCTGGGAGTA -3" and reverse as "5-CCTTATGAAGATACAGGCTAGTTGA -3" with product size of 174bp fragment

The PCR was done by using commercial thermal cyclerfrequencymachine(Swift™MaxProSWT-MXP-BLC-4)with47.7%, 7specific protocol according to annealing temperature of(Table3)Table [1]: Distribution of study participant according to study group

the primers.

The PCR amplification product was separated on agarose gel and visualized through gel documented system. PCR products were sent for sequencing to Macro gene Europe Laboratory.

Result

In the present study 44 (46.8%) were selected as cases and 50 (53.2%) were selected as control group (Table 1). The most affected age group was 25-34 year 16 (36.4%), followed by 35-40 years 15 (34.1%) (Table2). the frequency of the abortion number in the case group; most of them had abortion for three time with frequency about 77.3 %, four times about 9.1%, five time 2.3%, six time 6.8% and nine time about 2.3% (Table 3). The frequency of their gestational age is; 11-14 week about 47.7%, 7-10 weeks about 34.1% and 6 weeks 18 % (Table3)

Sequencing result

The sequencing results were analyzed using different bioinformatics soft-wares and tools for MTHFR C677T. The obtained sequences aligned using BioEdit-ClustalW software with a normal sequence from GenBank gene (accession number NC_000001.11in NCBI).

When the cases were compared with the normal reference the single Base Exchange was found C>T While when the controls were compared with normal reference, no any single base exchange was found among the all control groups (figure 7,8). when used the mutation taster software the mutation was predicted

(figure 9).

For MTHFD (G1958A) sequences aligned using BioEdit-ClustalW software with a normal sequence from GenBank gene (accession number NC_0000014.91in NCBI). When the cases were compared with the normal reference tow single Base Exchange were found T>A and G>A While when the controls were compared with normal reference, no any single base exchange was found among the all-control groups (figure 10,11) and the mutation taster soft warewas predicted T>A mutation (figure 12).

Discussion

several studies have evaluated whether a correlation between the C677T and A1298C polymorphisms of the methylenetetrahydrofolate reeducates (MTHFR) gene and a higher risk of recurrent pregnant loss (RPL), only few studies that evaluated the correlation between the MTHFD (rs2236225) (G1958A) and recurrent miscarriage. This study was aimed to detect the MTHFR (C667T) and MTHFD (G1958A) polymorphisms among Sudanese women with the recurrent miscarriages

In the present study 44 women were selected as cases and 50 apparently healthy women were selected as control group. The most affected age group was 25-34 year 16 (36.4%), followed by 35-40 years 15 (34.1%). The frequency of the abortion number in the case group; most of them had abortion for three time with frequency about 77.3 %, the frequency of their gestational age is; 11-14 week about 47.7%, 7-10 weeks about 34.1% and 6 weeks 18 %, 97% of theses pregnancies were un planned, this highlight lack of pre pregnancy counseling for these women generally this big issue in Sudan but at least it should be provided for high-risk group like women with RPL.

The PCR result shows that about 40 (90%) for MTHFR (C677T) allele was positive in the cases and only12 (24%) were positive or the control group. For MTHFD (G1958A) allele 42 (95%) were positive in the case group and about 14 (28%) were positive in the control. When compared between case and control for the tow alleles there was highly significant differences.

The sequencing results revealed; when the cases were compared with the normal reference the single Base Exchange was found C>T While when the controls were compared with normal reference, no any single base exchange was found among the all-control groups, in addition to that when used the mutation taster software the mutation was predicted.

Park et al reported; MTHFR catalyzes irreversible conversion of 5,10-methylentethrahydrofolate to 5methiltethrahydrofolate (CH3-THF). The normal activity of MTHFR aids to maintain folate and methionine in the bloodstream at constant levels, preventing Hcy accumulation. Polymorphisms in the gene encoding MTHFR may lower its enzymatic activity. The variant C677T leads to a substitution of a cytosine into a thymine at position 677 within exon 4 of the MTHFR gene. This genetic variant leads to an amino acidic substitution in position 222 [6]

In the other hand Domenico et al said; the C677T variant of the MTHFR gene does not appear to influence predisposition to miscarriage in the first or second trimester of pregnancy. Thus, it may be unadvantageous to analyze them for diagnostic aims. However, daily intake of folic acid remains an important therapeutic practice for pregnant women in order to reduce the risk of congenital defects among other complications [8]. This study finding disagree with the study by Al-Achkar et al; in 206 women with URPL versus healthy women showed an increased risk for RPL in individuals carrying the MTHFR 677T allele and the homozygous genotype 677TT. Also, in the other study which used larger samples size showed that; the frequency of the T allele of the MTHFR 677 locus in the URPL group was also statistically significantly higher than that in the control group, indicating that the MTHFR 677T allele is a risk factor for URPL, which is consistent with the results of the study by Al-Achkar et al [9].

Mtiraoui et al; analyzed genetic polymorphisms in women with RPL and found that the risk of developing URPL in women carrying the homozygous mutant genotype (CC) was increased. Klai et al.; also found that women with the mutated gene have an increased risk of miscarriage and other pregnancy complications [10,11]. For MTHFD (G1958A) gene sequences results showed; when the cases were compared with the normal reference tow single Base Exchange were found T>A and G>A, while when the controls were compared with normal reference, no any single base exchange was found among the all-control groups and the mutation taster software was predicted T>A mutation.

Parle-McDermott et al reported; a polymorphism [1958G \rightarrow A (R653Q, dbSNP rs2236225] within the gene encoding the trifunctional enzyme MTHFD1 (5,10-methylenetetrahydrofolate dehydrogenase, 5,10-

methenyltetrahydrofolate cyclohydrolase, 10formyltetrahydrofolate synthetase) is a maternal risk for severe placental abruption, a maternal risk for having a pregnancy affected by a neural tube defect (NTD) and is possibly involved in fetal in viability [12].

In addition, Anne Parle-McDermott etal said; identified the MTHFD1 1958AA genotype as an independent maternal risk factor for unexplained pregnancy loss during the second trimester of pregnancy [13].

Conclusion

In the conclusion our research result showed highly significant association between the MTHFR C667T, MTHFD G 1958 A polymorphisms and RSA in the Sudanese women, according to this result the MTHF polymorphisms might become one of the main causes of unexplained diagnosis women with recurrent spontaneous abortion.
